Between hope of life and spirituality with resilience in the agents of Sabzevar city

Summary :

The present study was conducted with the aim of predicting the relationship between resilience and hope for life and spirituality in disabled people. This research was of applied type and correlational descriptive method. The statistical population of this research included all disabled people with a file and a medical commission approved in Sabzevar welfare department (8000 people) in 1402; Among them, 367 people (176 men and 191 women) from the disabled were selected using a simple sampling method, and its instruments included the spirituality questionnaire of Parsian and Donining (2006), the resilience questionnaire of Connor and Davidson (2003) and the hope questionnaire. Schneider's Life (1991) was completed by disabled people. In the statistical analysis of this research, Spss 24 software and Pearson correlation coefficient and multiple regression analysis were used simultaneously. The obtained results showed that there is a significant relationship between life expectancy and spirituality with resilience in the disabled people of Sabzevar city. The life expectancy variable can positively predict resilience in disabled people. Also, the components of life expectancy and the components of spirituality each separately have a significant positive relationship with resilience, and the component of strategic thinking from the variable of life expectancy has the largest role in predicting resilience among the components of life expectancy and It has spirituality. Therefore, it can be concluded that the two variables of life expectancy and spirituality which together predict 50.4% of resilience can increase resilience.
